1 Introduction

Given the opportunity to review the design document and related smart contract source code of the Token Vesting support in Okse, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About Okse

Okse is a decentralized non-custodial system built to revolutionize the financial market. The audited Token Vesting support implements a much-needed airdrop mechanism, which allows users to stake their JulD token to farm OKSE token.

Table 1.1: Basic Information of Okse Token Vesting

Item	Description
Target	Okse Token Vesting
Type	EVM Smart Contract
Language	Solidity
Audit Method	Whitebox

1.2 About PeckShield

PeckShield Inc. [7] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

Impact \ Likelihood	*High*	*Medium*	*Low*
High	Critical	High	Medium
Medium	High	Medium	Low
Low	Medium	Low	Low

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [6]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further

Table 1.3: The Full List of Check Items

Category	Check Item
Basic Coding Bugs	Constructor Mismatch
	Ownership Takeover
	Redundant Fallback Function
	Overflows & Underflows

	Making Type Inference Explicit
	Adhering To Function Declaration Strictly
	Following Other Best Practices

deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [5], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functionality that processes data.
Numeric Errors	Weaknesses in this category are related to improper calculation or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
Time and State	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
Error Conditions, Return Values, Status Codes	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper management of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logics	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

2 Findings

2.1 Summary

Here is a summary of our findings after analyzing the `Token Vesting` implementation. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	0	
Low	2	
Informational	0	
Total	2	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 2 low-severity vulnerabilities.

Table 2.1: Key Okse Token Vesting Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Incompatibility With Deflationary/Rebasing Tokens	Business Logic	Confirmed
PVE-002	Low	Trust Issue Of Admin Keys	Security Features	Mitigated

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 | Detailed Results

3.1 Incompatibility With Deflationary/Rebasing Tokens

- ID: PVE-001
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: `JulDAirdrop`
- Category: Business Logic [4]
- CWE subcategory: CWE-841 [2]

Description

In the `Token Vesting` implementation, the `JulDAirdrop` contract is the main entry for interaction with users. In particular, one entry routine, i.e., `deposit()`, accepts the deposits of the supported assets. Naturally, the contract implements a number of low-level helper routines to transfer assets in or out of the `JulDAirdrop` contract. These asset-transferring routines work as expected with standard ERC20 tokens: namely the vault's internal asset balances are always consistent with actual token balances maintained in individual ERC20 token contracts.

```
    function deposit(uint256 amount) external nonReentrant depositEnable {
        address userAddress = msg.sender;
        TransferHelper.safeTransferFrom(
            juldAddress,
            userAddress,
            address(this),
            amount
        );
        userBalances[userAddress] = userBalances[userAddress].add(amount);
        emit UserDeposit(userAddress, amount);
    }
```

Listing 3.1: `JulDAirdrop::deposit()`

However, there exist other ERC20 tokens that may make certain customizations to their ERC20 contracts. One type of these tokens is deflationary tokens that charge certain fee for every `transfer()` or `transferFrom()`. (Another type is rebasing tokens such as `YAM`.) As a result, this may not meet the assumption behind these low-level asset-transferring routines. In other words, the above operations, such as `deposit()`, may introduce unexpected balance inconsistencies when comparing internal asset records with external ERC20 token contracts.

One possible mitigation is to measure the asset change right before and after the asset-transferring routines. In other words, instead of bluntly assuming the amount parameter in `transfer()` or `transferFrom()` will always result in full transfer, we need to ensure the increased or decreased amount in the contract before and after the `transfer()` or `transferFrom()` is expected and aligned well with our operation. Though these additional checks cost additional gas usage, we consider they are necessary to deal with deflationary tokens or other customized ones if their support is deemed necessary.

Recommendation If current codebase needs to support possible deflationary tokens, it is better to check the balance before and after the `transfer()`/`transferFrom()` call to ensure the book-keeping amount is accurate. This support may bring additional gas cost. Also, keep in mind that certain tokens may not be deflationary for the time being. However, they could have a control switch that can be exercised to turn them into deflationary tokens. One example is the widely-adopted `USDT`.

Status The issue has been confirmed by the team. The team decides to leave it as is considering there is no need to support deflationary/rebasing token.

3.2 Trust Issue Of Admin Keys

- ID: PVE-002
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: `Multiple Contracts`
- Category: Security Features [3]
- CWE subcategory: CWE-287 [1]

Description

In the `Token Vesting` protocol, there is a privileged account that plays a critical role in governing and regulating the protocol-wide operations (e.g., configuring various system parameters). In the following, we show the representative functions potentially affected by the privilege of the account.

```
    function setTimesAndSwapRate(bytes calldata signData, bytes calldata keys)
        external
        nonReentrant
        validSignOfOwner(signData, keys, "setTimesAndSwapRate")
    {
        (, , , bytes memory params) = abi.decode(
            signData,
            (bytes4, uint256, uint256, bytes)
        );

```

```
        (
            uint256 _depositStartDate,
            uint256 _depositEndDate,
            uint256 _withdrawStartDate,
            uint256 _withdrawDuration,
            uint256 _swapRate
        ) = abi.decode(params, (uint256, uint256, uint256, uint256, uint256));
        require(_depositEndDate > _depositStartDate, "deposit time invalid");
        require(
            _withdrawStartDate > _depositEndDate,
            "withdraw start time invalid"
        );
        require(
            _depositEndDate.add(_withdrawDuration) > _withdrawStartDate,
            "withdraw duration invalid"
        );
        depositStartDate = _depositStartDate;
        depositEndDate = _depositEndDate;
        withdrawStartDate = _withdrawStartDate;
        withdrawDuration = _withdrawDuration;
        swapRate = _swapRate;
        emit TimesAndSwapRateUpdated(
            depositStartDate,
            depositEndDate,
            withdrawStartDate,
            withdrawDuration,
            swapRate
        );
    }

    // verified
    function setTokenAddress(bytes calldata signData, bytes calldata keys)
        external
        nonReentrant
        validSignOfOwner(signData, keys, "setTokenAddress")
    {
        (, , , bytes memory params) = abi.decode(
            signData,
            (bytes4, uint256, uint256, bytes)
        );

        (address _juldAddress, address _okseAddress) = abi.decode(
            params,
            (address, address)
        );

        juldAddress = _juldAddress;
        okseAddress = _okseAddress;
        emit AddressUpdated(juldAddress, okseAddress);
    }
```

Listing 3.2: `JulDAirdrop`

We emphasize that the privilege assignment may be necessary and consistent with the protocol design. Though the `multi-sig` mechanism could greatly alleviate this concern, it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed `DAO`-like structure.

Recommendation Promptly transfer the privileged account to the intended `DAO`-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status The issue has been confirmed by the team. The `multi-sig` mechanism will mitigate this issue.

4 Conclusion

In this audit, we have analyzed the `Token Vesting` design and implementation in `Okse`, which is a decentralized non-custodial system built to revolutionize the financial market. The audited `Token Vesting` support implements an airdrop mechanism, which allows users to stake their `JulD` token to farm `OKSE` token. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
